Table of contents

Abstract

The Emissions Database for Global Atmospheric Research provides emission time series from 1970 until 2018 for CO_2 and until 2015 for non-CO_2 GHGs for all countries. This report is contributing to the Paris Agreement process with an independent and quantitative view of global GHG emissions.

Foreword

Tackling climate change is one of the most important challenges that the international community is currently facing. Policy makers, scientists and citizens around the world are increasingly aware of the urgent need to implement climate change mitigation policies in order to keep global mean temperature increases below 1.5 C, demanding concrete and realistic actions from policy makers.

The European Union, as a signatory of the Paris Agreement (2015), has set ambitious targets in terms of greenhouse emission reductions. These targets are also a key topic of the future Commission political agenda, which has the ambition for Europe to become the first carbon neutral continent by 2050. However, climate change abatement requires a global effort to act and monitor emission reduction policies. Consequently, the development of transparent and consistent emission inventories at global scale becomes crucial for the identification and assessment of undertaken measures.

While energy related activities are and will remain a major source of greenhouse gas emissions at the global level, in the latest decades the European Union has succeeded in decoupling the energy sector from the economic growth. Indeed, as highlighted by the last report on the state of the Energy Union, the transition to a modern, low carbon and energy-efficient economy is underway, and Europe is on a credible pathway to meeting its Paris Agreement commitments.

Such a success is based on the comprehensive policy design developed in recent years, including the newly approved "Clean energy for all Europeans package" providing a view to the EU's long-term strategy of achieving carbon neutrality by 2050. The overall Energy Strategy goal of making energy in Europe more secure, affordable and sustainable contains harmonized pieces of sectorial legislation directly impacting inter alia the carbon footprint of the energy produced, traded and consumed across the Union.

In such a context of rapid regulatory changes, it is essential that the European Commission, in addition to developing its legislative framework, equips itself with transparent and state-of-the-art tools, as the Emissions Database for Global Atmospheric Research (EDGAR), a global greenhouse gas inventory developed by Joint Research Centre. Such a tool has widely demonstrated its value and will be crucial in monitoring and understanding how specific measures may influence or have influenced emission trends at the global scale, providing policy decision makers with feedback on the actual effectiveness of regulation updates needed to meet EU and global climate targets.

Acknowledgement

This booklet was produced with input from many colleagues, gathered over several years. The International Energy Agency (IEA) energy use statistics are fundamental to the EDGAR database and the authors would like to thank IEA (R. Quadrelli, F. Mattion) for the continuing collaboration. The authors would also like to thank United States Geological Survey (USGS) (R. Schulte, L. Apodaca), International Fertiliser Association (IFA) (M. Prud'homme), oil and gas company BP plc and Global Gas Flaring Reduction Partnership (GGFR)/(U.S. National Oceanic and Atmospheric Administration (NOAA), for the provision of data. The authors are grateful to the Directorate-General for Climate Action (DG CLIMA) (T. van Ierland, M. Perry, O. Gippner) for their reviews and guidance. An extra thanks to the colleagues, J. Wilson, F. Dentener, A. Santoro and T. Vandyck for their thorough reviews and proof-reading.

Executive summary

Policy context

In the context of the 2030 Energy and Climate framework, the European Union has currently set a target of reducing its greenhouse gas emissions by at least 40% compared to the 1990 levels. By 2050, further reductions are needed if the European Union is to become climate-neutral, as outlined in the European Commission's Clean Planet for All vision (1) and mentioned by the President-elect of the European Commission in her Agenda for Europe.

The European Union climate mitigation policies not only cover the largest emitting gases (CO_2, CH_4, N_2O), but also the fluorinated greenhouse gases, as well as emission and absorption of the land use and forestry sectors. Together they aim of cutting these emissions by at least 40% by 2030 compared to the 1990 levels in order to meet the EU's Nationally Determined Contribution to the Paris Agreement. Also other countries are in the process to define and implement policies to deliver on their Nationally Determined Contributions.

In order to track the progress in GHG emission reduction strategies, the Paris Agreement has set the transparency framework under which all Parties are requested to implement bottom-up inventories of the national GHG emissions and to report them to the United Nations Framework Convention on Climate Change (UNFCCC). Reported emission inventories, however, do not cover the entire globe, have data gaps for specific sectors, and lack decades-long time series.

The European Commission's in-house Emissions Database for Global Atmospheric Research (EDGAR) fills these gaps, completing the global picture with time-series for each country, contributing to enhanced transparency and providing a benchmark against which national and global estimates can be compared. The current version of the EDGAR database (EDGARv5.0_FT2018) contains estimates of fossil CO_2 emissions from 1970 to 2018, while estimated non-CO_2 GHGs (CH_4, N_2O and F-gases) emissions are provided from 1970 to 2015.

EDGAR estimates are based on the latest available global statistics and state-of-the-art scientific knowledge of emission mechanisms for a wide range of anthropogenic activities. The methodology used is fully transparent and in line with both the most recent scientific literature and Intergovernamental Panel on Climate Change (IPCC) recommendations. This combination of reliability, independence and completeness makes EDGAR a valuable quantitative tool to support the complex international scientific and political discussions on climate mitigation. In particular, EDGAR data can contribute to providing a comprehensive picture needed for the UNFCCC's Global Stocktake of 2023. The previous two editions of this booklet (2017, 2018) have been presented to the annual Conference of Parties (COP) under UNFCCC.

Key conclusions

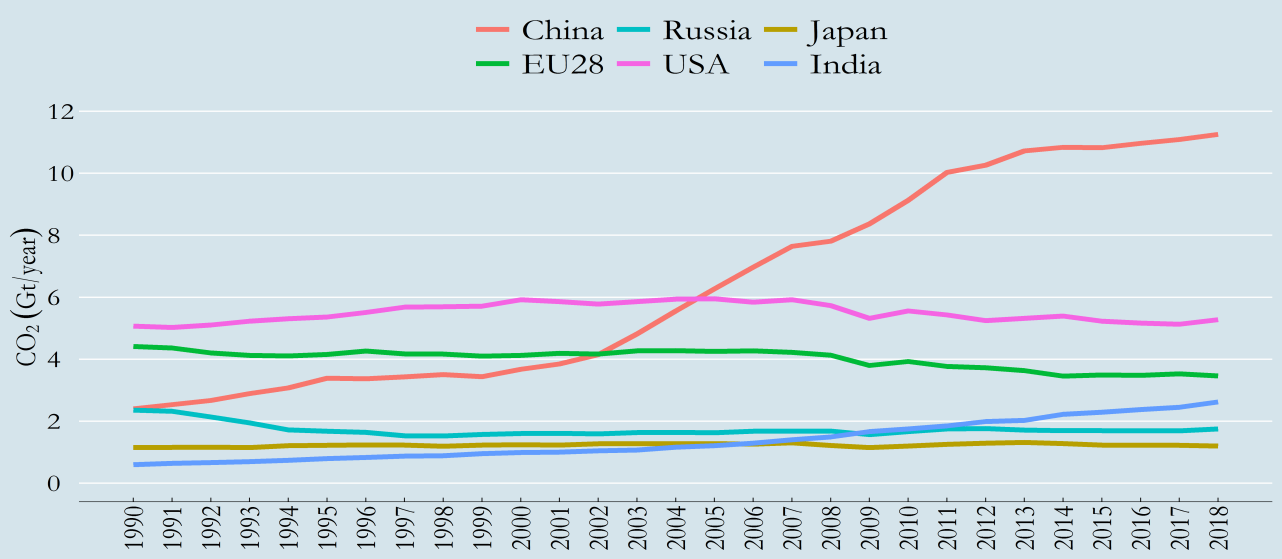
In preparing the latest edition of this booklet, the EDGAR database has been updated to provide emission time series from 1970 until 2018 for anthropogenic fossil CO_2 (2) and from 1970 until 2015 for anthropogenic non-CO_2 GHG emissions. This year, the booklet features for the first time fluorinated gases (F-gases) (3) together with the greenhouse gases CO_2, CH_4 and N_2O that were already covered in previous editions.

Globally, the increase of CO_2 and other GHG emissions, in the period 2016 and 2017, continued in 2018. The EDGAR time series shows that the European Union and Russia were the only industrialised economies (among the major emitting regions) whose GHG emissions are significantly below 1990 levels. European Union GHG emissions were 19.3% lower in 2015 and fossil CO_2 emissions 21.6 % lower by 2018 compared to 1990. By comparison, the United States and Japan increased both their CO_2 and GHG emissions by 4-5% compared to 1990 levels, while the emerging economies of China and India have respectively 3.7 and 3.4 times more CO_2 emissions in 2018 compared to 1990, due to their rapid industrialisation in the past two decades.

Main findings

Since the beginning of the 21st century, global GHG emissions have grown in comparison to the three previous decades, mainly due to the increase in CO_2 emissions from China, India and other emerging economies. The latest estimates from EDGAR confirm the continuation of this trend in 2018, with global anthropogenic fossil CO_2 emissions increasing by 1.9% compared to 2017, to reach 37.9 Gt CO_2.

Figure 1. Fossil CO_2 emissions of the major emitting economies.



(2) In this study the fossil CO_2 emissions include emissions from fossil fuel combustion (coal, oil and gas), from fossil fuel use (combustion, flaring), industrial processes (cement, steel, chemicals and urea) and product use; no short-cycle carbon CO_2 emissions are included for any sector.

(3) Fluorinated gases (F-gases) include: Sulfur hexafluoride (SF6), Nitrogen trifluoride (NF3), Perfluorocarbons (PFCs: CF_4, C_2F_6, C_3F_8, c-C_4F_8), Hydrofluorocarbons (HFCs: HFC-125, HFC-134a, HFC143a, HFC-152a, HFC-227ea, HFC-23, HFC-236, HFC-245, HFC-32, HFC-365mfc, HFC43-10-mee). Other fluorinated compounds such as chlorofluorocarbons (CFC) and hydrochlorofluorocarbons (HCFC) are also potent greenhouse gases. However, CFCs and HCFCs are not included in EDGAR inventory because since 1990 under the Montreal Protocol they have been phased-out and replaced by HFCs.

In 2018, China, the United States, India, the EU28, Russia and Japan - the world's largest CO_2 emitters - together accounted for 51% of the population, 65% of global Gross Domestic Product World Bank (2019), 80% of total global fossil fuel consumption (BP, 2019) (4) and emitted 67.5% of total global fossil CO_2. Emissions from these five countries and the EU28 show different changes in 2018 compared to 2017: the largest increase in the emissions between 2017 and 2018 is found for India (+7.2%), followed by Russia (+3.5%), the United States (+2.9%) and China (+1.5%). By comparison, both the EU28 (-1.9%) and Japan (-1.7%) reduced their fossil CO_2 emissions. Compared to 1990, EU28 fossil CO_2 emissions were 21.6% lower in 2018 at 3.46 Gt CO_2, representing 9.1% of the global share and equivalent to 6.8 t CO_2/cap/yr in per-capita terms.

Trends vary also across the other 11 countries with more than 1% share of total global fossil CO_2 emissions, showing decreases of 4.5% in Germany, 2.3% in Mexico, 1.3% in Brazil, 1.1% in Saudi Arabia and 0.1% in Canada, and increases of 0.6% in Turkey, 0.9% in Australia, 1% in South Africa, 2.9% in Korea, 4.8% in Iran and Indonesia. Emissions from international aviation and shipping increased by 1% and 2% respectively compared to 2017, and are in 2018 equivalent to 3.3% of total global fossil CO_2 emissions.

Anthropogenic GHG emissions are dominated by fossil CO_2 emissions, and also increased steadily over the period 1990-2015 from 32.8 to 49.1 Gt CO_2eq/yr, an overall increase of approximately 50%. Global per capita GHG emissions decreased in the 1980s and 1990s to a minimum in 2001 of 5.7 t CO_2eq/cap/yr but have increased by 13.4% from 2000 to 2015 to reach 6.7 t CO_2eq/cap/yr.

We have estimated that emission changes are accurate to within ±0.5% (Olivier et al., 2016) when based on robust statistical activity data (e.g. IEA energy balance data for 1970-2015) and up to 2% for the data for 2016-2018 (based on a Fast-Track (5) approach), depending on regional, sectorial and fuel contributions. Uncertainty for other GHGs is much higher than for the reported CO_2 and strongly dictated by the contribution of highly uncertain processes to the national total (Janssens-Maenhout et al., 2019). These uncertainties should be considered when using these data for any kind of analysis by readers of this booklet and policy makers.

(4) Defined as the sum of all coal, liquid fossil fuel and natural gas consumption.

(5) International activity data, mainly energy balance statistics of IEA (2017) for 1970-2015 were used to estimate CO_2 from fossil fuel consumption. These emissions are extended until 2018 using a sectorial (IEA) and fuel (BP) dependent Fast-Track approach. As a consequence, emissions for the last three years are characterized by higher uncertainty. Further details on the Fast Track methodology are provided in Annex 1.

Related and future JRC work

The reliability, independence and completeness of the EDGAR GHG emissions data make them a valuable quantitative tool to support the complex international scientific and political discussions on climate mitigation. The EDGAR database compiles global greenhouse gas and air pollutant emissions making use of international global statistical data sources and of a globally consistent methodology across countries, whereas national inventories represent the official emissions data reported by the EU Member States to the European Environmental Agency which are used for tracking policy targets. Therefore, the objectives of the EDGAR database are: to inform policy makers and the scientific community involved in the field of GHG emissions and budgets; complement and support the compilation of national inventories and the coming UNFCCC Global Stocktake; underpin analyses of the co-benefits of air pollution and GHG emission mitigation strategies; interpretation of satellite data and understanding of emission uncertainties. In addition, the EDGAR framework and the JRC experience in compiling emissions inventories are shared and compared within the international emissions community of the Global Emissions InitiAtive (GEIA).

While this booklet summarises data for GHG emissions for 1970-2018, it should be noted that EDGAR is a comprehensive global emission database, including both GHG and air pollutant emissions for all countries. The EDGAR GHG emissions reported in this booklet will be used by Working Group Three on mitigation of the next Intergovernmental Panel on Climate Change (IPCC) Assessment Report. EDGAR also supports the IPCC Task Force on National Greenhouse Gas Inventories, compiling and refining guidelines for national GHG emission inventories and providing training support and knowledge databases to visualise emission hot spots. Finally, EDGAR is also supporting the Arctic Council's 'Arctic Monitoring and Assessment Programme' (AMAP) by providing CH_4 and mercury emission data.

Quick guide

For each country, a fact sheet is provided with time series of fossil CO_2 and GHG emissions from all anthropogenic activities except land use, land-use change, forestry and large-scale biomass burning. The upper panel of the fact sheet includes fossil CO_2 annual totals from 1990 until 2018 by sector, together with emissions per capita and per GDP ([6]). The second panel shows GHG emissions from 1990 to 2015 by substance (CO_2, CH_4, N_2O and F-gases) expressed as CO_2 equivalent calculated using the 100-year global warming potential (GWP -100) previously used in the IPCC 4th Assessment report (AR4) ([7]). An overview table with total emissions by country for the years 1990, 2005, 2015 and 2018 is also reported, together with per capita and per GDP emission data. Finally, the bottom panel of each fact sheet shows the changes in CO_2 and GHG emissions by sector for the last available year (2018 or 2015) compared to 1990 and 2005.

([6]) Gross Domestic Product in US Dollars expressed in 2011 Purchasing Power Parity.

([7]) The latest UNFCCC revision of the reporting guidelines adopted by COP (2014) decided to use from 2015 onwards the global warming potential coefficients over a period of 100 years (GWP-100) in IPCC's Fourth Assessment Report (IPCC AR4, 2007) with 25 for CH_4 and 298 for N_2O, to calculate GHG emissions in terms of CO_2 equivalent.

Introduction

Scope

In December 2015, the Paris Agreement brought "all nations into a common cause to undertake ambitious efforts to combat climate change" and required all parties to the agreement to put forward their best efforts through "nationally determined contributions". Acknowledging the need to ensure environmental integrity, a transparency framework was created and 5-yearly Global Stocktakes from 2023 onwards were planned.

The Emissions Database for Global Atmospheric Research (EDGAR) contributes to global climate action with an independent and quantitative view of global GHG emissions. EDGAR is a global database that estimates country and sector specific emissions of CO_2 and other greenhouse gases implementing a fully transparent state-of-the-art methodology. As such, it supports efforts to provide a consistent, transparent emissions estimate that is global in scope and can inform climate action under the Paris Agreement, although the conception and early versions of EDGAR precede by far the Paris Agreement.

This report gives a country by country overview of fossil CO_2 and GHG emissions as estimated by EDGAR. In particular, it provides fossil CO_2 emission estimates until 2018 based on robust statistical data and a consolidated Fast Track (FT) methodology. Due to the lack of comparable updates for relevant sectors for non-CO_2 GHG (e.g. agricultural activities, product use, chemicals production, etc.), the overall greenhouse gas time series are provided until 2015.

A key feature of this booklet is the improved analysis of the F-gas emissions. This family of gases are regulated by the Kyoto Protocol and are also included in the Parties' commitment under the Paris Agreement. Furthermore, in October 2016 in Kigali, the Montreal Protocol was amended to include also a phase-down the use of HFCs. As a result, industrialised countries started the phase-down already on the 1st of January 2019, while most of the developing countries will start their HFCs phase-down in 2024. The EU Regulation on F-gases (No 517/2014) implements an EU-wide phase-down for HFCs, which started in 2015, with the aim of cutting emissions by two thirds by 2030 in the EU compared with 2014. Therefore, an overview of current F-gas emissions is urgently needed to monitor the emission reductions foreseen for the next years at the global scale.

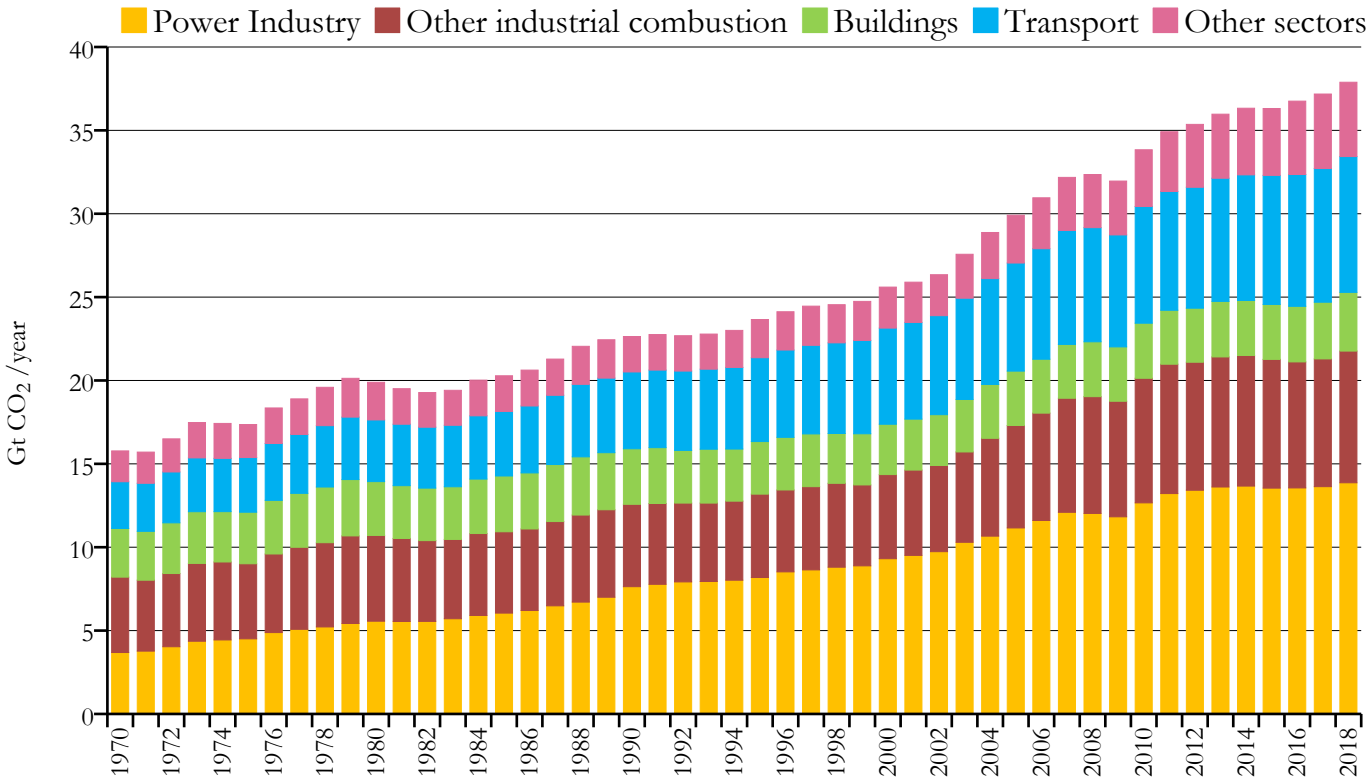
Overview

Trends of global fossil CO_2 emissions and of the major emitting countries and the EU28 from 1990 to 2018 are presented, followed by the corresponding GHG emissions from 1990 to 2015. Then, a fact sheet with both fossil CO_2 and GHG emission time series, per capita and per GDP data and sector specific trends is presented for every country. Details on the bottom-up methodology applied for the EDGAR emission compilations are then reported together with the data sources and references used. Finally, concluding remarks are also provided. Additional analyses can be found in the companion publication "Trends in Global CO_2 and Total Greenhouse Gas Emissions – 2019 Report" by Olivier et al. (2019).

Global Fossil CO_2 Emissions from 1990 until 2018

The global annual emissions of fossil CO_2 in Gt CO_2/yr are illustrated in Fig. 2 for the entire time series of the EDGAR database (1970-2018). Shares of emissions originating from the main activity sectors (namely power industry ([8]), other industrial combustion ([9]), transport ([10]), buildings and other sectors ([11])) are also presented. Figure 3 shows the total annual fossil CO_2 emissions for the EU28 and the three largest emitting countries. Per capita CO_2 emissions (in t CO_2/cap/yr) for the EU28 and the same top emitting countries are represented in Fig. 4.

Figure 2. Total global annual emissions of fossil CO_2 in Gt CO_2/yr by sector. Fossil CO_2 emissions include sources from fossil fuel use, industrial processes and product use (combustion, flaring, cement, steel, chemicals and urea).



([8]) Includes power and heat generation plants (public and autoproducers).

([9]) Includes combustion for industrial manufacturing and fuel production.

([10]) Includes road transport, non-road transport, domestic aviation and inland waterways for each country. International shipping and aviation also belong to this sector and are presented separately before the country fact-sheets due to their international feature.

([11]) Includes industrial process emissions (non-metallic minerals, non-ferrous metals, solvents and other product use, chemicals), indirect emissions (for N_2O only), agriculture (including agricultural soils, agricultural waste burning, enteric fermentation, manure management) and waste.

As shown in Figs. 3 and 4, EDGAR data include uncertainty bands that estimate the random uncertainty inherent in the emission estimates. The uncertainty takes stock of accuracy of both activity statistics and of the emission factor per type of fuel. Uncertainty estimates use the tiered estimate model suggested by the Intergovernmental Panel on Climate Change (IPCC, 2006). It should be noted that the uncertainties in emissions calculated with the Fast Track approach (i.e., fossil CO_2 emissions for 2016-18) are likely higher for individual sectors and countries due to the assumptions behind this methodology. We have estimated that emission changes are accurate to within ±0.5% (Olivier et al., 2016) when based on robust statistical activity data (e.g. IEA energy balances data for 1970-2015) and up to 2% for the Fast-Track data for 2016-2018 depending on regional, sectorial and fuel contributions. This should be considered when using these data for any kind of analysis.

Figure 3. Total annual emissions of fossil CO_2 in Gt CO_2/yr for the EU28 and large emitting countries with uncertainty (coloured bands).

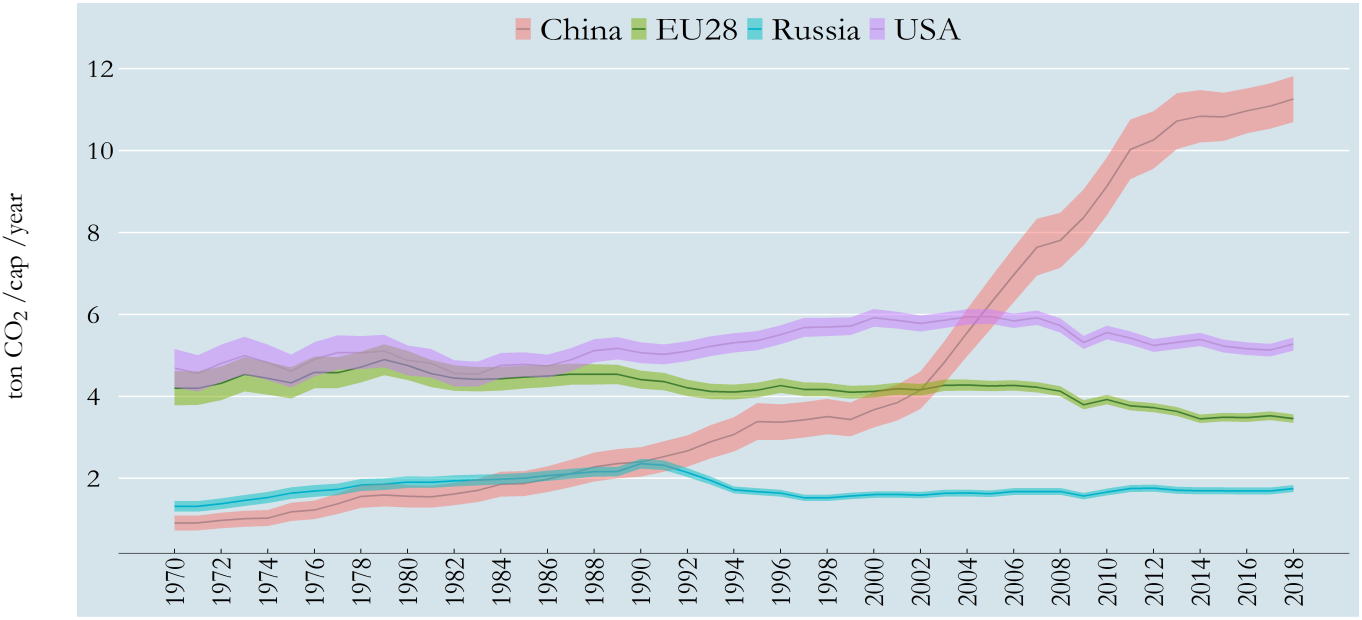


Figure 4. Per capita CO_2 emissions (in t CO_2/cap/yr) from fossil fuel use, industrial processes and product use for the EU28 and large emitting countries with uncertainty (in coloured bands) and for the world average.

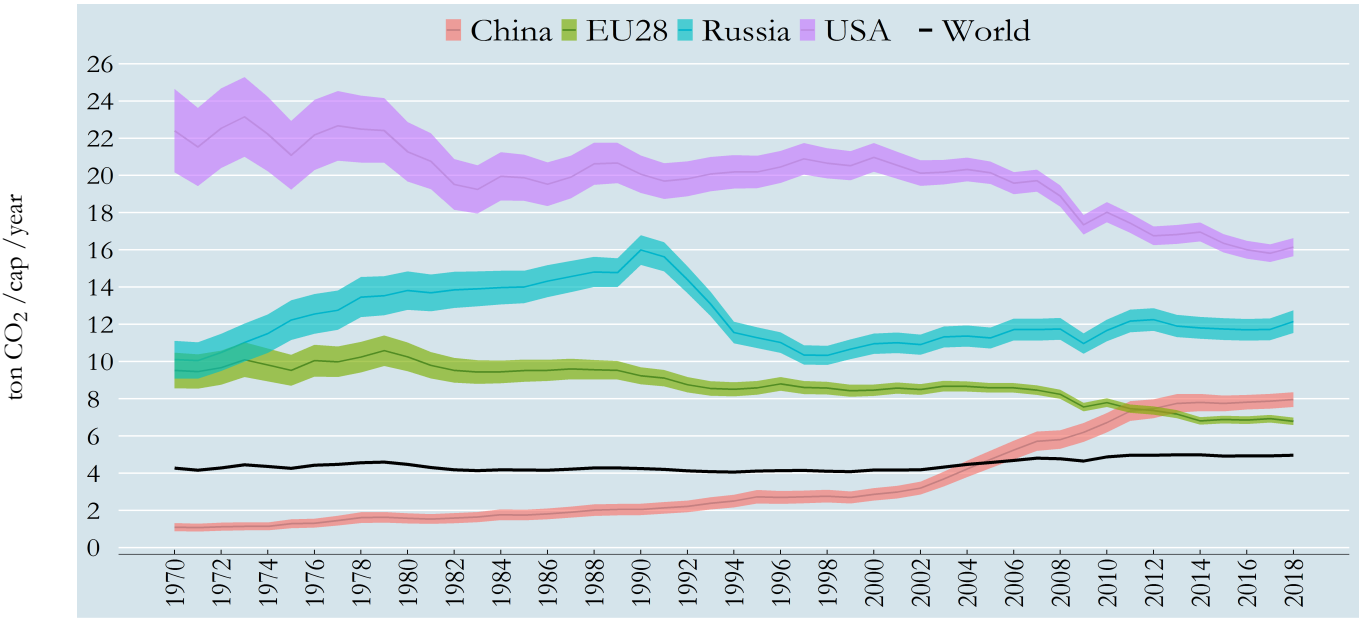

Global fossil CO_2 emissions in 2018 increased by 1.9% to a total of 37.9 Gt CO_2, continuing the increasing trend observed between 2016 and 2017 (+1.2%). By comparison, 2015 and 2016 were years with no, or limited growth in global emissions (0.0% in 2015 and 0.4% in 2016). Table 1 provides a global overview of the CO_2 emission change between the years 2017 and 2018 for top emitting countries. Among the major CO_2 emitting countries, only the European Union (by 1.9%) and Japan (by 1.7%) reduced emissions in 2018, representing shares of 9.1% and 3.2% respectively of the global total. China (1.5%), the United States (2.9%), Russia (3.6%) and India (7.2%) all increased their emissions in 2018, representing 29.7%, 13.9%, 4.6% and 6.9% respectively of the global total. Outside the larger emitting countries, the largest increases are observed for Iran by 4.8% (1.9% share), South Korea by 2.9% (1.8% share) and Indonesia by 4.8% (1.5% share). Global CO_2 per capita emissions have increased by ca 17% from 4.25 t CO_2/cap/yr to 4.97 t CO_2/cap/yr between 1990 and 2018.

Among the EU Member States, Germany, responsible for 2% of the global emissions, had the largest reduction (4.5%). Besides the European Union and Japan, the largest percentage reductions are seen in Mexico (representing 1.3% of the global total) with a 2.3% reduction and Brazil (representing 1.3% of the global total) with a 1.3% reduction.

Table 1. Global share in 2018 and change in fossil CO_2 emissions for top emitting countries (contributing for more than 1% each to the global total) between 2017 and 2018. Light blue shading highlights countries with CO_2 emissions increasing by more than 1% between 2017 and 2018. The average annual change since 2015 (%) representing a longer trend is also reported.

Top emitting countries	Global share	Change between 2017 and 2018	Average annual % change since 2015
China	29.7%	1.5%	1.3%
United States	13.9%	2.9%	0.3%
EU28	9.1%	-1.9%	-0.3%
India	6.9%	7.2%	4.7%
Russia	4.6%	3.6%	1.1%
Japan	3.2%	-1.7%	-0.8%
Iran	1.9%	4.8%	5.3%
South Korea	1.8%	2.9%	2.9%
Saudi Arabia	1.6%	-1.1%	0.9%
Canada	1.6%	-0.1%	0.3%
Indonesia	1.5%	4.8%	4.4%
Brazil	1.3%	-1.3%	-1.8%
Mexico	1.3%	-2.3%	0.6%
South Africa	1.3%	1.0%	0.0%
Turkey	1.1%	0.6%	4.6%
Australia	1.1%	0.9%	1.1%
International shipping	1.8%	2.0%	2.2%
International aviation	1.5%	1.0%	2.0%

EU28 total fossil CO_2 emissions have decreased over the past two decades, such that emissions in 2018 are 21.6% lower than in 1990 and 18.7% lower than in 2005 ([12]). The EU28 share of the global total emissions decreased from 9.6% to 9.1% between 2015 and 2018. In 2018 the EU28 emitted 3.5 Gt CO_2, corresponding to 6.8 t CO_2 per person. A closer look to recent trends shows that a stalling in 2016 has been followed by an increase of 1.3% in 2017 and by a decrease of 1.9% between 2017 and 2018. In terms of sectors and countries, in 2018, CO_2 emissions from fossil fuel combustion in the power industry decreased by 2.1% in the EU with the largest reductions for Portugal (7.7%), Bulgaria (6.7%), Germany (4.8%) and Italy (3.2%). Conversely, lime production emissions increased by 2.4% for the same period. Among the EU28 countries, in 2018 the largest contributor to the EU28 CO_2 emissions was Germany with 21.8%, followed by the United Kingdom (10.8%), Italy (10%), Poland (9.7%), France (9.4%) and Spain (8%). The shares of coal, oil and gas in total fossil fuel consumption in the EU28 were 18%, 51% and 31%, respectively. Reductions in fossil fuel consumption were observed in 2018: coal: 5.1%, oil: 0.4% and gas: 1.5% drop compared to the year before. These consumption reductions contributed to decreases in CO_2 fossil emissions which were especially noticeable in Portugal (7.9%), Bulgaria (6.8%), Germany (5.0%), Italy (3.3%), France (2.7%), Sweden (2.6%), Spain (2.4%), Malta (2.4%), the United Kingdom (2.2%) and The Netherlands (2.1%). In most of these countries, the reductions were also a consequence of swapping from coal and liquid fossil fuel to less carbon intense energy sources.

China's fossil CO_2 emissions, after a slight decrease in 2015 (-0.1%) increased in 2016 by 1.3%, in 2017 by 1.1% and in 2018 by 1.5% reaching 11.3 Gt CO_2. The equivalent per capita CO_2 emissions (8 t CO_2/cap/yr) in 2018 are 18% higher than the European average, while CO_2 emissions per GDP unit, amount to about 499 kg CO_2 /1000 USD(PPP)/yr, i.e., the highest of the top-15 emitting countries. The increase in Chinese emissions in 2018 is mainly due to increases in oil and gas consumption of 5.0% and 17.7%, respectively, while coal consumption increased only slightly by 0.9%; the shares of oil, gas and coal in fossil fuel consumption were 23.0%, 8.7% and 68.3%. The sectors contributing most to the fossil CO_2 emissions in China are power generation (41%) and other industrial combustion (24%); in 2018 the emissions from these sectors increased by 1.3% and 1.9%, respectively.

([12]) As mentioned in the executive summary, EDGAR emission estimates provide the global context needed for the upcoming UNFCCC Global Stocktakes, complementing officially reported national emission inventories. Therefore, the EDGAR data are not those used to track the accomplishment of EU reduction policies.

Emissions of fossil CO_2 of the **United States** in 2018 increased by 2.9% from 2017, reversing the decreases seen since 2015. Total fossil CO_2 emissions in 2018 accounted for approximately 5.3 Gt, with 95% emitted by combustion sources. The inter-yearly increase of CO_2 emissions was driven by higher oil (1.9 %) and natural gas consumption (1.1%). Compared to peak emissions in 2005, 2018 emissions are 11% lower (but still higher than the 1990 levels), whereas the population has increased by over 10% over the same period. Total CO_2 emissions fell by about 3.1% in 2015 and 1.9% in 2016, mainly because of reduced coal consumption for power generation (BP, 2019). In 2018, the value of emissions per unit of GDP was 290 $kgCO_2$/1000 USD(PPP)/yr, the same as in 2017, after 7 years of reductions. Emissions per capita have on the contrary increased by 2% compared to 2017 to reach 16.1 t CO_2/cap/yr.

India's fossil CO_2 emissions continued to increase to 2.6 Gt CO_2 in 2018, 7.1% more than in 2017, the second largest increase in the last five years and above the average annual increase of 4.5% per year for the period 2014–2018. India's emissions already surpassed those of Russia in 2009. With a share of 6.9% of total global CO_2 emissions in 2018, India is the fourth largest emitting economy after China, the United States and the EU28. However, India's per capita emissions of 1.9 t CO_2/cap/yr are about four times lower than China and the EU28, about eight times lower than United States and lower even than the average per capita emissions of many developing countries. A major contribution to India's growing emissions comes from the 7.5% increase in fossil fuel consumption, 61.1% of which is supplied by coal. Annual coal consumption, mostly domestically produced, increased by 8.7% whereas annual oil consumption increased by 5.3% according to BP (2019).

Russia's fossil CO_2 emissions, after six years of steady decreases at the average rate of 0.6% per year, increased in 2018 by 3.5% (60 Mt of CO_2) to reach about 1.7 Gt, while GDP increased by 2.3% compared to 2017. With a share in global CO_2 emissions of 4.6% in 2018, Russia is the fifth largest emitter after China, the United States, EU28 and India. The increase in 2018 CO_2 emissions was mainly due to an increase in consumption of coal by 4.9%, natural gas by 5.4% and oil by 0.5% (BP, 2019). Russian per capita emissions of 12.1 t CO_2/cap/yr are higher than those of China (by 53%), EU28 (by 79%) and Japan (by 29%) and 25% lower than those of the United States.

After stagnation in 2017, **Japan** saw fossil CO_2 emissions fell by 1.7% in 2018, in contrast to the slight increase in GDP between 2016 and 2017 (1.7%) and a substantial plateau between 2017 and 2018. Japanese fossil CO_2 emissions accounted for 1.2 Gt CO_2 in 2018, representing 3.2% of global CO_2 emissions. A decrease in the consumption for the three main fuel types was observed, mainly driven by lower oil consumption. Japan's per capita emissions in 2018 of 9.4 t CO_2/cap/yr are of the same order of magnitude as those of the Netherlands (9.5) and slightly higher than those of Germany (9.15).

Global Greenhouse Gas Emissions from 1990 until 2015

The non-CO_2 greenhouse gases considered in this report together contribute around 26% to the 2015 global GHG emissions measured in this report ([13]), an amount comparable to the CO_2 emissions of the largest emitting single country (China). Therefore, although global CO_2 emissions are by far the largest contributor to the accumulation of GHGs in the atmosphere, the contribution of the other gases considered in this section is considerable.

EDGARv5.0 provides emission estimates also for non-CO_2 greenhouse gases from 1970 until 2015 using entirely international statistics, in particular for CH_4, N_2O and fluorinated gases (F-gases). Total GHG emissions are summed in CO_2 equivalent (CO_2eq) using the GWP-100 metric of AR4. GHG emissions for the major emitting countries and regions are briefly described, as well as the per capita and per GDP trends. For a more detailed description of our findings for the EU28 and the five largest emitting countries, we refer to Olivier et al. (2019). Uncertainty for GHGs is much higher than for CO_2 and strongly dictated by the contribution of highly uncertain processes to the national total (Janssens-Maenhout et al., 2019).

Global GHG emissions are dominated by the fossil CO_2 share and increased steadily over the entire period 1990-2015 from 32.8 to 49.1 Gt CO_2eq/yr, with an overall increase in total GHG emissions of ca 50%. Non-CO_2 GHG emissions continue to increase in absolute terms, though their share in total global emissions appears to be declining. Per capita GHG emissions decreased in the 1980s and 1990s to a minimum of 5.7 t CO_2eq/cap/yr but have since increased by 13.4% from 2000 to 2015 to reach 6.7 t CO_2eq/cap/yr. In 1990 CH_4 and N_2O emissions accounted for 23.6% (7.7 Gt CO_2eq) and 6.3% (2.1 Gt CO_2eq) of the global total, respectively, but these shares decreased to 18.8% (9.2 Gt CO_2eq) and 5.2% (2.6 Gt CO_2eq) by 2015, respectively. These patterns can be explained by the changes in the economic structure of most emerging economies, moving from agricultural societies, with a large share of N_2O and CH_4 emissions coming from agricultural activities to industrialised economies, with significant increases in fossil CO_2 emissions from the energy and industrial sectors. By comparison, F-gases doubled their share of the global GHG total from 1.1% (0.3 Gt CO_2eq) in 1990 to 2% (ca 1 Gt CO_2eq) in 2015. The main driver of the growth in the emission of F-gases is the use of hydrofluorocarbons (HFCs) as alternatives to ozone depleting substances (e.g. hydrochlorofluorocarbons (HCFCs) and chlorofluorocarbons (CFCs)), banned under the Montreal Protocol since the beginning of the 90s.

([13]) Noting that emissions from land use, land-use change and forestry are not included.

EU28 GHG emissions have decreased since the eighties and the 4.5 Gt CO_2eq/yr GHG emissions in 2015 is a reduction of 21.7% compared to 1990. In the seventies, emissions were characterised by an increase of 12% over the entire decade, whereas in the eighties and nineties they fell by 8% and 9% respectively. GHG emissions from the EU28 are dominated by fossil CO_2 emissions which are more than three quarters of the total GHGs (ranging from 77.7% to 81.7% over the 1990-2015 period). The CH_4 contribution to total GHG emissions varies from 12.7% to 15.7% and it is mainly from the agricultural sector (enteric fermentation and manure management, representing 41.1 % of CH_4 emissions in 2015), waste treatment and disposal (representing 30.2% of CH_4 emissions in 2015) and production of coal and gas (representing 15.8 % of CH_4 emissions in 2015). In 2015, the top six emitting countries, responsible for 65% of EU28 CH_4 emissions are United Kingdom (17.3%), Germany (12.9%), France (10.7%), Poland (10.3%), Spain (7%) and Italy (6.7%). CH_4 emissions from the agricultural sector went down by 23%, from 0.33 Gt CO_2eq/yr to 0.26 Gt CO_2eq/yr between 1990 and 2015. At the European level, CH_4 emissions from landfill have been falling from 1996 onwards; however, individual countries have behaved differently. With the exception of Spain and Cyprus, most Western EU countries significantly reduced their CH_4 emissions from landfills over time, while Eastern EU countries (in particular Romania, Slovakia, Hungary and Czechia) had stable or increasing emissions. CH_4 fugitive emissions from coal and gas production are also falling, with most of the reductions associated with the production of coal in Poland, Romania, Germany and United Kingdom, while increasing emissions from the gas production sector are seen in several EU countries. N_2O emissions represent between 6.1% and 7.9% of the total greenhouse gas emissions in the 1990-2015 period and are produced mainly from agricultural soils (representing 46.2% of N_2O emissions in 2015) and the chemicals industry (adipic and nitric acid production, representing 13.8% of total N_2O). In 2015, the six top emitting countries, France (14.4%), Germany (14.3%), Poland (9.6%), United Kingdom (9.4%), Spain (8.1%) and Italy (6.0%) were responsible for more than 60% of N_2O emissions in the EU. In 2015, F-gases contributed with 0.12 Gt CO_2eq representing 3.5% of EU28 GHG emissions. Despite the absolute increase in HFCs (the main group of the F-gases) emissions from 1990 to 2015, the percentage change in the emissions per year has been decreasing over the same time period. In 2015, for the first year, HFCs emissions are stabilized ([14]), reflecting the implementation of the new EU Regulation on F-gases (No 517/2014). The per capita emission of GHG in the EU28 in 2015 is of 8.9 t CO_2eq/cap/yr. The effect of non-CO_2 GHGs on the per capita value was to raise the CO_2 alone per capita emissions by ca 29% in 2015.

([14]) The latest EEA report on F-gases (https://www.eea.europa.eu/publications/fluorinated-greenhouse-gases-2018, European Environmental Agency) confirms that in 2015 HFCs have started declining and in 2016 they have decreased by 0.1% compared with the previous year.

China's GHG emissions increased almost 6.6 times between 1970 and 2015, from 2 Gt CO_2eq/yr in 1970 to 13.1 Gt CO_2eq/yr in 2015. The contribution of CH_4 in total CO_2eq fell from 47.6% in 1970, to 30.4% in 1990 and 11.9% in 2015, whereas for N_2O they were 7.3%, 7.3% and 3.1%, respectively. Overall the contribution of non-CO_2 GHG to total CO_2eq decreased considerably from 55.1% in 1970 to 44.9% in 1990 and 17.2% in 2015, showing the relative increase in industrial versus agriculture development on GHG emissions since 1970. Non-CO_2 GHGs add ca 21% to both per capita emissions and per GDP CO_2eq emission in 2015. F-gases with 0.28 Gt CO_2eq/yr contribute a further 2.2% to Chinese GHG emissions.

In 2015 **United States**' GHG emissions reached 6.4 Gt CO_2eq and were dominated by fossil CO_2 emissions, which contributed 81.1% of the total. CH_4 had the second largest share representing 9.8% of US GHG emissions, while N_2O and F-gases contributed for 4.6% and 4.5%, respectively. CH_4 is mainly emitted by agricultural activities (enteric fermentation and manure management: 34.7% in 2015), fugitive emissions from the production of oil gas and coal (42.3% in 2015), and the waste sector (waste water treatment and landfills: 18.8% in 2015). N_2O is mainly emitted by activities related to the agricultural soil sector and the production of chemicals (adipic and nitric acid production). The per capita emission of GHG in the United States in 2015 is 20.1 t CO_2eq/cap/yr. Non-CO_2 GHGs comprise 23.3% of the per capita CO_2eq emissions in 2015.

India's GHG emissions reached 3.3 Gt CO_2eq/yr in 2015, compared with 0.8 and 1.4 Gt CO_2eq/yr in 1970 and 1990, respectively. The CH_4 share fell from 61% in 1970 to 47% in 1990 and 25% in 2015. Over the same period, the share of N_2O emission also fell from 9.4% to 9.2% and then to 6%. India experienced a noticeable shift from 1970, when non-CO_2 GHGs accounted for a 71% share of overall GHG emissions, falling to 31% by 2015, mostly due to a decreasing share of agricultural activities in Indian economy. The per capita emission of GHG in India in 2015 is of 2.6 t CO_2eq/cap/yr. Non-CO_2 GHGs comprise 46.4% of the per capita CO_2eq emissions in 2015. The same figure was above 70% in 2006. F-gases represent a minor contribution to Indian's GHG, with a 0.8% share in 2015.

Russia's GHG emissions fell by 27% from 1990-2015 after an increase of 69.8% from 1970 to 1990. This corresponds to a change in GHG emissions from 1.8 Gt CO_2eq/yr in 1970 to 3 Gt CO_2eq/yr in 1990, falling back to 2.2 Gt CO_2eq/yr in 2015. The shares of CH_4 for these three years in total CO_2eq emissions in Russia were 19%, 16.8% and 19.4%, whereas for N_2O were 5.7%, 3.6% and 3.3%, respectively. The per capita emission of GHG in Russia in 2015 is of 15.5 t CO_2eq/cap/yr. Non-CO_2 GHGs comprise about 32% of the per capita and per GDP CO_2eq emissions in 2015. In 2015, F-gases contributed with 0.03 Gt CO_2eq representing 1.4% of Russian GHG emissions.

Japan's GHG emissions have increased slowly over the past decades: in 1990 and 2015 the levels of emissions were 1.3 and 1.4 Gt CO_2eq/yr, respectively. The shares of CH_4 emission in those two years were rather stable representing ca 6% of Japanese GHG emissions (0.06 Gt CO_2eq), whereas for N_2O decreased from 2.2% in 1990 to 1.4% in 2015. Per capita GHG emissions in Japan in 2015 are of 10.6 t CO_2eq/cap/yr. The effect of non-CO_2 GHGs on per capita emission is to raise the CO_2 alone per capita emissions by 10.7% in 2015. In 2015, F-gases contributed with 0.06 Gt CO_2eq representing 4.4% of Japanese GHG emissions.

Conclusions

The Emissions Database for Global Atmospheric Research (EDGAR) is a comprehensive inventory of anthropogenic emission time series from 1970 until 2018 for CO_2 and until 2015 for other GHGs. An IPCC-based bottom-up emission calculation methodology is applied to all countries, demonstrating that consistent inventories can be developed for all countries within the limitations of the quality of the available statistical data. EDGAR complements the data prepared by most of Annex I (15) countries (mostly industrialised countries) that can count on a good statistical data infrastructure and regular reporting system to the UNFCCC. In the case of countries with less developed statistical data infrastructure, EDGAR can provide useful information for their future emission inventory requirements, by providing an independent estimate, methodological tools and expertise to support country efforts in developing their own inventory. In particular, the time series of EDGARv5.0_FT2018 can provide the emissions trend information for non-Annex I (16) countries that will be needed for the UNFCCC's Global Stocktake in 2023. EDGARv5.0_FT2018 provides an important input to the analysis of global CO_2 trends with its 48-year time series.

Analysis of the EDGAR time series shows that since the beginning of the 21st century GHG emissions have increased compared to the three previous decades, mainly driven by the increase in CO_2 emissions from countries with emerging economies. EDGARv5.0_FT2018 shows that global fossil CO_2 emissions from anthropogenic activities, excluding biomass burning and the land use, land-use change and forestry sector have, after stagnating in 2014-2015, increased by 1.9% between 2017 and 2018, reaching a total of 37.9 Gt CO_2. Compared to 2017, CO_2 emissions in the United States increased by 2.9% in 2018 and in China by 1.5%, while they decreased in the EU28 by 1.9%. Overall, EU28 CO_2 emissions have decreased over the past two decades, reaching in 2018 a total of 3.5 Gt CO_2, representing reduction levels of 21.6% compared to 1990 and 18.7% compared to 2005. The EU28 emission reduction determined a decreasing share on the global total, from 9.6% to 9.1% between 2015 and 2018, reaching an average 6.8 t CO_2/cap/yr which is above the global per capita average (4.97 t CO_2/cap/yr).

Global GHG emissions are dominated by fossil CO_2 and increased steadily over the entire period 1990-2015 by about 50% from 32.8 to 49.1 Gt CO_2eq/yr. Per capita GHG emissions decreased in the 1980s and 1990s to a minimum of 5.7 t CO_2eq/cap/yr but have then increased by 13.4% from 2000 to 2015 to reach 6.7 t CO_2eq/cap/yr.

(15) Annex I countries under the UN Framework Convention on Climate Change: Australia, Austria, Belarus, Belgium, Bulgaria, Canada, Croatia, Czechia, Denmark, European Union, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Japan, Latvia, Liechtenstein, Lithuania, Luxembourg, Monaco, Netherlands, New Zealand, Norway, Poland, Portugal, Romania, Russia, Slovakia, Slovenia, Spain, Sweden, Switzerland, Turkey, Ukraine, United Kingdom, United States.

(16) Non-Annex I countries are developing countries, under the Kyoto Protocol without legally binding emissions reductions targets.

Annexes

Annex 1: Bottom-up methodology for the emissions compilation

The basis for the fossil CO_2 time series presented in this report is EDGARv5.0, which covers the period 1970-2017 (Muntean et al., 2018). Emissions of non-CO_2 GHGs, namely CH_4, N_2O and F-gases are provided for the period 1970-2015 (http://edgar.jrc.ec.europa.eu/overview.php?v=booklet2019; Lo Vullo et al. (2019); Olivier et al. (2018)).

In EDGAR, emissions per country and compound are calculated on an annual basis and sector wise by multiplying the country-specific activity and technology mix data by country-specific emission factors and reduction factors for installed abatement system for each sector.

For the greenhouse gas emission factors, the default values recommended in the IPCC 2006 guidelines were used: global values for CO_2 from fuel combustion, and where recommended, region-specific values were applied for other sources.

All human activities leading to climate relevant emissions are included, except biomass/biofuel combustion (short-cycle carbon) in the power, industry, buildings, transport and agricultural sectors, large-scale biomass burning and land use, land-use change and forestry (LULUCF). EDGAR makes use of the IPCC sectorial classification and a consistent bottom-up emission calculation methodology is applied to all countries, so that emissions of different countries can be compared, considering their respective levels of detail, uncertainties or data limitations. In particular for developing countries with less robust and systematic statistical data infrastructures and limited experience in reporting their fossil fuel emissions inventories, EDGAR can provide information and support them in complying with their inventory preparation.

EDGARv5.0_FT2018 uses international activity data, mainly energy balance statistics of IEA (2017) for 1970-2015 to estimate CO_2 from fossil fuel consumption. CO_2 emissions are extended with a Fast Track approach until 2018 using BP statistics that assumes the same sectoral breakdown as in the last year of the IEA energy balance statistics for 2015. A consequence of this approach is that the emissions for the Fast Track years (2016-2018) reported in this booklet may not be comparable with those reported in subsequent editions of this booklet, where they are based on future releases of the definitive IEA energy balance statistics.

Updates for 2016, 2017 and 2018 for cement, lime, ammonia and ferroalloys production are based on USGS statistics, urea production and consumption are based on IFA statistics, associated gas used from flaring from GGFR/NOAA (2019), steel production from world steel and cement clinker production from UNFCCC (2019b). For the other sectors with lower contributions to the global CO_2 emissions, the time series have been extended for the period 2015-2018 using proxy data and relative changes in activity data compared to 2015, reported in recent data sources.

For energy: detailed IEA (2017) activity data are used to calculate CO_2 emissions for the period 1970-2015. The recent trends in coal, oil and natural gas consumption reported in the BP Review of World Energy (BP, 2019) are used to calculate the relative changes beyond 2015 for CO_2 only. For oil consumption, BP figures were corrected for road biofuel use (fuel ethanol and biodiesel) which are included in the BP oil consumption data for road transport. For the change in international transport, we apply the reported change in oil consumption per country according to BP for the historically most contributing countries to global marine and aviation fuel sales.

For the fugitive emissions: CO_2 emissions from coke production for 2015 to 2018 follow the same relative change as reported for the crude steel production of world steel (2019). CO_2 flared at oil and gas extraction for 1994 onwards was based on the total amount of gas flared derived from satellite observation of the intensity of flaring lights per country (GGFR/NOAA, 2019).

For the metal industry: the largest contribution is from blast furnaces, which in addition to the CO_2 emissions from blast furnace gas combustion accounted for under the energy sector, emit also CO_2 from the coke/coal input as reducing agent and limestone used in for iron and steel production. Here the crude steel production statistics reported by World Steel Association (worldsteel, 2019) are used as input to calculate CO_2 emissions. Ferro-alloys production data from USGS are used to update the activity data in EDGARv5.0 up to 2015 and for more years (2016, 2017 and 2018) further updates are performed by using the pig iron production trends.

For non-metallic minerals: CO_2 emissions from carbonates used in cement clinker production are based on reported or estimated cement clinker production. Cement production was calculated from cement production reported by the USGS (2019), except for China in 2018 (NBSC, 2019). Next, the clinker-to-cement ratio is based on the clinker production data until 2016 from UNFCCC (2019) for so-called Annex I countries and for China from the China Cement Almanac (CCA, 2016) and from 2011 onwards from the China Cement Research Institute (CCRI, 2019). For four other countries (India, Brazil, Egypt and Thailand), we used clinker production ratios from the Cement Sustainability Initiative database "Getting the Numbers Right" of the World Business Council for Sustainable Development (WBCSD, 2018). The changes in the lime production from USGS (2019) are applied to extrapolate CO_2 emissions from all other carbonate uses (glass production etc.). With regards to the feedstock use for chemicals production, the ammonia production from USGS (2019) is used, except for urea consumption and production, where data are provided by the International Fertiliser Industry Association (IFA, 2019). It is assumed that small soil liming emissions follow the gross ammonia production trend.

For waste: CH_4 and N_2O emissions from wastewater handling have been updated until 2015 based on IPCC (2006) methodology as described in Janssens-Maenhout et al. (2019) by using updated statistics from FAO (2019) for production of meat, pulp, sugar and for average protein supply, and from UN (2019) and RFA (2019) for alcohol production. Urban and rural population data are from UNDP (2019). GHGs emissions from waste incineration without energy recovery have been updated for the following categories: biogenic, clinical, sewage sludge, industrial solid waste, municipal solid waste and other (non-specified) waste with data from UNFCCC (2019a) complemented by the approach recommended in IPCC (2006). The amount of landfilled waste has been updated by considering the latest data presented in UNFCCC (2019a) for Annex I countries, with data from UN statistics UN (2019) for some developing economies and by using the 2000 per capita value suggested in IPCC (2016) when no up to date information was available.

For agriculture: agricultural activities comprise the application of urea and agricultural lime, enteric fermentation, rice cultivation, manure management, fertiliser use (synthetic and manure), agricultural waste burning (in field). Large-scale biomass burning from savannah is not included in the current work. Emissions from the agricultural sector are estimated using activity data for from FAOSTAT (2018) together with emission factors from IPCC Guidelines (2006). CH_4 emission factors for enteric fermentation of dairy and non-dairy cattle have been updated including the IPCC 2006 Tier 2 methodology.

For the countries belonging to "Other Africa" ([17]), "Other Non-OECD Asia" ([18]) and "Other Non-OECD Americas" ([19]) in the IEA classification: the share of CO_2 emissions from all these countries in global total is very small e.g. in 2015, according to IEA, this was about 0.25%. IEA provides only aggregated activity data for these three groups of countries. Compared to the previous EDGAR version (v4.3.2), in EDGARv5.0 a new methodology was developed to allocate the activity data from IEA (2017) to each single country by using splitting factors derived from US EIA (2018) country specific data on fuel consumption of coal, oil and natural gas. Together with the IEA (2017) updates, this newly developed methodology mostly explains the differences between CO_2 time series for these countries in EDGAR v4.3.2 and v5.0 versions. Consequently, the uncertainties in CO_2 emission estimations for these countries are larger than for other countries, in particular for the sectorial subdivision; additional reliable data and information are needed to improve the activity data allocation for them.

([17]) Includes Botswana (until 1980); Burkina Faso; Burundi; Cape Verde; Central African Republic; Chad; Comoros; Djibouti; Equatorial Guinea; Eswatini; Gambia; Guinea; Guinea-Bissau; Lesotho; Liberia; Madagascar; Malawi; Mali; Mauritania; Namibia (until 1990); Niger (until 1999) Réunion; Rwanda; Sao Tome and Principe; Seychelles; Sierra Leone; Somalia and Uganda.

([18]) Includes Afghanistan; Bhutan; Cambodia (until 1994); Cook Islands; East Timor; Fiji; French Polynesia; Kiribati; Lao People's Democratic Republic; Macau, China; Maldives; Mongolia (until 1984); New Caledonia; Palau (from 1994); Papua New Guinea; Samoa; Solomon Islands; Toga and Vanuatu.

([19]) Includes Antigua and Barbuda; Aruba; Bahamas; Barbados; Belize; Bermuda; British Virgin Islands; Cayman Islands; Dominica; Falk-land Islands (Malvinas); French Guiana; Grenada; Guadeloupe; Guyana; Martinique; Montserrat; Puerto Rico (for natural gas and electricity); Saba (from 2012); Saint Eustatius (from 2012); Saint Kitts and Nevis; Saint Lucia; Saint Pierre and Miquelon; Saint Vincent and the Grenadines; Sint Maarten (from 2012); Suriname (until 1999) and the Turks and Caicos Islands.

Annex 2: Fluorinated gases (F-gases)

EDGARv5.0_FT2018 includes, among other substances, the fluorinated gases (F-gases), a class of man-made chemicals used in a wide range of industrial applications. The F-gases play an important role in some key sectors of the economy, such as the production of magnesium and aluminium or the semiconductor manufacturing. Fluorinated greenhouse gases (F-gases) represent a set of powerful greenhouse gases which is significantly contributing to climate change.

F-gases include three main groups : (1) Hydrofluorocarbons (HFCs) mainly used as refrigerants, blowing agents for foams and solvents; (2) Perfluorocarbons (PFCs) used in the electronics sector (3) sulphur hexafluoride (SF6) used mainly as insulating gas, in high voltage switchgear and in the production of magnesium and aluminium (refer to Table 2). Emissions from less known sources like military use and accelerators are also included based on Oliver et al. (2018).

Table 2. Overview on F-gases by sector included in EDGARv5.0_FT2018.

The methodology applied to calculate F-gas emissions in EDGAR is described in detail in Lo Vullo et al. (2019) and Olivier et al. (2018). The activity data included in EDGARv5.0_FT2018 for the F-gases are gathered from public activity data collected in the national statistics and reports of national environmental agencies or trade associations. From 1990 activity data are available in the context of UNFCCC national submissions.

The main source of information for the emission factors is the IPCC emission factor database (EFDB, 2006) ([20]), that provides default emission factors for each emitting category, based on scientific literature. EDGARv5.0 includes for some industrial sectors, specific emission factors provided by the producer's association, like the aluminium producers, better representing the real conditions of the production processes. For the aluminium production, since the mid-2000s, the technological landscape has been changing. The technology update in EDGAR is still in progress and for this reason the PFC emissions could be overestimated for the time period 2006-2015 (Lo Vullo et al., 2019). Country specific emission factors are also provided by the National Inventory Report (NIR) in the UNFCCC submissions.

Non-ferrous Metal Production: The main data sources used for updating the activity data are the United Framework on Climate Change national submissions (UNFCCC, 2017) and the primary aluminium production data from the United States Geological Survey Minerals Yearbook (USGS, 2016). Information from the International Aluminium Institute (IAI, 2016) is included for PFC emission factors.

Electronics Industry: The main data sources used for updating the activity data are the United Framework on Climate Change national submissions (UNFCCC, 2017) and the World Semiconductor Council (WSC, 2016) reports.

Chemical Industry: The main data sources used for updating the activity data are the United Framework on Climate Change national submissions (UNFCCC, 2017) and the United Nations Environment Programme report on HFC-23 production (UNEP, 2017).

Electrical Equipment: The data sources used for updating the activity data are mainly from the United Framework on Climate Change national submissions (UNFCCC, 2017).

([20]) In May 2019 a refinement of emissive categories was adopted by the IPCC 49th Session.

Annex 3: Construction of country fact-sheets

For each country, a fact sheet is provided with time series of fossil CO_2 and GHG emissions from all anthropogenic activities except land use, land-use change, forestry and large scale biomass burning.

The upper panel of the fact sheet includes the fossil CO_2 annual totals from 1990 until 2018 per sector, the fossil CO_2 per capita and per GDP (GDP is Gross Domestic Product in US Dollar expressed in 2011 Purchasing Power Parity). An overview table with total emissions by country for the years 1990, 2005, 2015 and 2018 is reported, together with per capita, per GDP emissions and population data. The bottom panel of each fact sheet shows the changes in emissions by sector in 2018 for CO_2 and in 2015 for GHGs compared to 1990 or 2005 levels. Along with the summary of the CO_2 and GHGs emission time series for each country, a graphical visualisation aids the interpretation of the CO_2 emissions change over time at the bottom of each page). The graphs compare CO_2 emissions for 2018 and 2015 for GHGs with the emission levels of two key years: 1990 (base year for national green-house gases inventory) and 2005, when the Kyoto Protocol came into effect. Emissions stalling, rising or dampening for the year 2018 are expressed in term of % change with respect to these two years, for sectors specified as follow:

Legend of the sectors:

 Power Industry - Power and heat generation plants (public & autoproducers)

 Other industrial combustion - Combustion for industrial manufacturing and fuel production

 Buildings – Small scale non-industrial stationary combustion

 Transport – Mobile combustion (road & rail & ship & aviation)

 Other sectors – Industrial process emissions & agriculture & waste

 indicates a reduction in 2018 (for CO_2) or in 2015 (for GHG) emissions by the amount expressed by the percentage value (in green)

 indicates growth in 2018 (for CO_2) or in 2015 (for GHG) emissions by the amount expressed by the percentage value (in red)

 In the cases where 2018 (for CO_2) or 2015 (for GHG) emissions have reduced or have grown by less than 5% with respect to the reference year, or have stalled, a horizontal orange arrow is shown. Also in this case the amount is expressed by the percentage value (in orange)

An "n/a" is used to indicate either a sector missing throughout the time series (meaning that no data are reported for that sector) or that no data are available for both the reference year and for 2018. Finally, in the instances when emissions from a specific sector have been reported for the reference year but not for 2018 a decreasing green arrow is shown without the associated percentage value (as for example [Power industry, Albania]; on the opposite, when emissions from a specific sector have been reported for 2018 year but not for the reference year, a rising red arrow is shown without the associated percentage value (as for example [Other industrial combustion, Malta]). Country-specific fossil CO_2 emission time series can be downloaded at the following website: https://edgar.jrc.ec.europa.eu/overview.php?v=booklet2019.

Annex 4: Fossil CO_2 and GHG emissions for the world and the EU28

Global totals for all countries, including international shipping and aviation, followed by the international transport sector (shipping and aviation).

Total EU28 emissions from Member States: Austria, Belgium, Bulgaria, Croatia, Cyprus, Czechia, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, United Kingdom.
